1 Project name

Cloud edge computing System using Wind River Linux with Kubernetes

2 Company

Wind River Systems

3 IP Requirements

The intellectual property of Wind River Systems including Wind River Linux cannot be shared with anyone who has not purchased a licence, given that statement, any code generated that uses an open source library will be shareable thanks to the GPL licence.

4 Problem Description

For years, systems have used a client-server type of architecture when thinking about a network focused system. These systems are useful but in general have a really problematic defect, latency. Latency is not that big of a problem is areas where a quick response is needed but in our growing world of IoT(internet of things) this is almost a requisite for a functional and fast system. This problem can be addressed by creating a system with layer in which the higher the layer the farther away the node is. If you need a quick and low latency task to be done by a node, the easiest way to reduce latency is to have the node as close as possible, like for example a cheap embedded system that is replicated around a city inside the area you live. The name of this solution is called Cloud Edge Computing.

5 General objective

Implement a solution using a Cloud Edge Computing Architecture comprised of three layers.

6 Specific objectives

6.1 First objective

Implement three layers of the system using Wind River Linux for the embedded devices.

6.2 Second objective

Generate an example to test the system.

6.3 Third objective

Compare using a simple latency test with a single server architecture.

7 Stakeholders

The stakeholders for this project include my supervisor as the most interested part and the company interested in having an implementation of a cloud edge computing with its products.

8 Solution description

This solution is divided in three layers that are interconnected and redirect traffic if necessary, the entrance of the system is the first layer.

8.1 First layer

The first layer is comprised of an embedded system or multiple embedded systems in which is works as the low latency entrance of the system. This layer is based on Wind River Linux and is used with kubernetes, in this case there are two options, k3s or OverC with kubernetes.

This layer is in charge of processing the request from the app and redirecting it to the next layer if necessary. This layer is also in charge of processing low latency critical tasks.

8.2 Second layer

The second layer is a server running on Linux in which is in charge of doing mid level processing tasks, it is also in charge of redirecting traffic to the third layer in case it is necessary. This layer is replicated less than the first layer but more than the third layer.

8.3 Third layer

This layer is the last layer and it is in charge of high level processing tasks. This layer is only one server in our case and in production it should be a couple more but still less than the second and first layer. This layer in general has the highest latency.

9 Deliverables and Criteria of acceptance

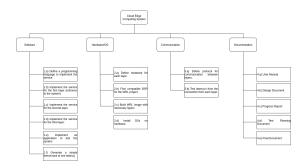

Figure 1: Work breakdown structure.

Table 1: Breakdown of work and its acceptance criteria

| To implement the service of the Cloud edge computing system, it is necessary to define a programming language. The options are C, C++ and Nodejs. 1.b Fully Implement the service in the first layer. 1.c Fully Implement the service in the second layer. 1.d Fully Implement the service in the second layer. 1.d Fully Implement the service in the third layer. 1.d Fully Implement the service in the third layer. 1.d Fully Implement the service in the third layer. 1.d Fully Implement the service in the third layer. 1.d Fully Implement the service in the third layer. 1.d Implement the image processing application to test the functionality of the system 1.e Define what hardware to use for each layer. 2.a Define what hardware to use for each layer. 2.b Based on the chosen embedded device, search for a compatible BSP. 3.a Define a protocol to connect the layers with low latency. 3.b Test latency's in between the connection of the layers. 4.a User manual 5 Supervisor validated. 4.b Design document 4.c Final document 5 Supervisor validated. | | Table 1: Breakdown of work and | |
